Abstract. *This research has proposed a switchable beam rectangular microstrip antenna with double parasitic patches, in which two PIN diodes were deployed for manipulation of the main beam direction and a superstrate (i.e. either a dielectric slab or metamaterial) for enhancement of the antenna gain. The dielectric slab is a second FR4 substrate while the metamaterial (MTM) is the 7×17 periodic structure of planar cycloid dipoles (PCD). Simulations were carried out and three different antenna prototypes (i.e. the proposed switchable beam rectangular microstrip antenna, the proposed antenna either with dielectric slab or MTM) fabricated and experimented. The simulation and experimental results are in good agreement and exhibit good impedance matching ($|S_{11}| < -10$ dB) along the operating frequency. The average measured gain is 7 dBi with the unidirectional radiation pattern along the operating frequency. The proposed switchable antennas with and without the superstrate are operable in the 2.4-2.5 GHz WLAN system and switchable in three directions of 0° , 30° and 330° (xy-plane). Moreover, the findings validate the applicability of either the dielectric slab or three MTM block-layers as the superstrate to improve the antenna gain.*

Keywords

Gain enhancement, metamaterial, microstrip, parasitic patch, PIN diode, switched beam, superstrate

1. Introduction

The exponential growth in smartphone use, together with the greater availability of budget internet-connected devices, has contributed to a phenomenon in which the demand for digital wireless communications outstrips the supply (i.e. capacity). In addition, the digital wireless technology suffers from the multipath fading effect where the waves reflect and scatter upon impacting the obstacles. According to [1], [2], these issues could be efficiently addressed with the utilization of a smart antenna, beam

steering antenna or switchable beam antenna.

In [1], the authors applied the path-diversity reception technique of the constant modulus algorithm (CMA) to an adaptive array antenna (AAA) to reduce the co-channel interference (CCI) in the terrestrial digital mobile communications. The aim was to efficiently utilize the frequency spectrum. In [2], a smart antenna based on the beamforming technique with spatial diversity using a fuzzy interference system and a neural network (NN) was proposed to reduce the signal loss associated with low beamforming. A genetic algorithm (GA) was used in the optimization of the fuzzy logic and NN, and the technique could achieve a lower side lobe level (SLL) than did the non-algorithm-integrated methods.

By comparison, the switchable beam antenna is less costly and of lower profile. Nevertheless, its beam steering is of discrete fashion. In [3], the switchable beam disc antenna was proposed for a wireless communications network. The main beam of the antenna could be rotated 360° around the azimuth angle and possesses a wide impedance bandwidth. The four elements of the slot antenna with single feed point were also presented. This antenna controls the main beam by alternating the ON/OFF state of four PIN diodes over the azimuth angle [4].

In [5], the authors proposed a switchable beam antenna using a printed circuit board (PCB) and an FR4 substrate with a square microstrip ring structure. A PIN diode was also utilized to manipulate the radiation pattern. In [6], the authors proposed a single-fed switchable beam antenna using the quasi-Yagi structure and a PIN diode to select an antenna director. Meanwhile, further improvements were made to the switchable beam antenna for the dual-band operation (2.4 GHz and 5.8 GHz) [7] using frequency selective surfaces [8]. In addition, several other components have been utilized to manipulate the antenna main beam, e.g. a transistor, field effect transistor (FET), and radio frequency microelectromechanical system (RF MEMS) switch [9], [10].

Wireless communications require a high-gain antenna, especially for the point-to-point and point-to-mul-

tipoint applications. Many gain improvement techniques have been proposed and experimented, e.g. the multilayer substrates or superstrates in the printed antenna [11], the metamaterial (MTM) to tune the impedance matching [12]. In addition, the multiband loaded monopole was integrated into the MTM to achieve the multiband operation for the WLAN/WiMAX applications [13]. In [14], the MTM was deployed in the design of an array antenna and thereby could suppress the mutual coupling while achieving the higher directivity. Moreover, the MTM was utilized to improve the impedance bandwidth [15], [17].

This current research proposes a switchable beam rectangular microstrip antenna with double parasitic patches. Two PIN diodes are deployed for manipulation of the main beam direction and a superstrate (i.e. either a dielectric slab or metamaterial) for enhancement of the antenna gain. The dielectric slab is a second FR4 substrate while the metamaterial (MTM) is the 7×17 periodic structure of planar cycloid dipoles (PCD). The proposed switchable antennas with and without the superstrate are operable in the 2.4-2.5 GHz WLAN system and switchable in three directions of 0° , 30° and 330° (xy -plane).

The organization of this research is as follows: Section 1 is the introduction. Section 2 deals with the proposed metamaterial (MTM), while Section 3 is concerned with the switchable beam antenna structure and design procedure. Section 4 discusses the deployment of the superstrate (either the dielectric slab or the MTM) to enhance the antenna gain. Three different prototype antennas and their respective experimental results are presented in Sec. 5. The concluding remarks are provided in Sec. 6.

2. The Configuration of Metamaterial (MTM)

Metamaterials (MTM) are synthetic periodic-structure materials with a negative refractive index n or with negative permittivity ϵ and permeability μ . MTM have been utilized in a variety of applications, including in ultra-wideband (UWB) antennas, monopole antennas, lens antennas and waveguides [15–17]. For double negative (DNG) media, the thin metal wire (TW) structure and the split ring resonator (SRR) structure are collectively employed for negative ϵ and μ .

Figure 1 illustrates the schematic of a *planar cycloid dipole* (PCD) of the MTM structure functioning as the DNG media. The PCD is fashioned from TW and SRR. In the study, a PCD was simulated under the normal incidence in a waveguide using CST Microwave Studio [18] and, due to its symmetrical characteristic, only S_{11} and S_{21} were investigated [19], [20].

Figure 2(a) illustrates $|S_{11}|$ and $|S_{21}|$ in dB within the frequency range of 1–4 GHz. In Fig. 2(a), $|S_{11}|$ and $|S_{21}|$ are at their respective peak and trough at about the frequency of 2.45 GHz, where the effective constitutive parameters

Parameter	Description	Physical Size (mm)
W_m	Total width of MTM	8.00
L_m	Total length of MTM	8.00
d_m	Cycloid diameter	6.80
t_m	Cycloid thickness	0.20
g_m	Distance between two dipoles	0.20
l_{dm}	Dipole thickness	0.15
l_{dm}	Dipole length	5.60

Tab. 1. The parameters and physical dimensions of the planar cycloid dipole.

could be extracted from the S parameters using the Nicolson-Ross-Weir (NRW) method [19], [20].

Based on Tab. 1, the simulated $|S_{11}|$ and $|S_{21}|$ were estimated and subsequently extracted for the real effective permittivity and permeability. In its design, the planar cycloid dipole (PCD) is mounted on an FR4 substrate

($\epsilon_r=4.3$) with a thickness of 1.8 mm. The simulation results indicated that the real effective permittivity and permeability of the PCD were both negative in the 2.43–2.5 GHz frequency range, as shown in Fig. 2(b).

3. Switchable Beam Antenna Structure

Figure 3 illustrates the schematic of the initial rectangular microstrip antenna whose feeding structure is that of a microstrip line. Initially, the microstrip feed line was simulated at the center frequency f_r of 2.45 GHz on an FR4 substrate ($\epsilon_r=4.3$) with a thickness h of 3.2 mm. The design of the feed line was carried out, whereby the patch antenna and the microstrip line match with the characteristic impedance of 50Ω [21]. The thickness t and length l_2 of the microstrip line were thus 6.16 mm and 17 mm, respectively. The position of the feed line was on one edge of the rectangular patch.

Meanwhile, the design of the rectangular patch was carried out using the transmission line model with the dominant mode (TM_{010}), as expressed in (1). The initial width W and length L of the rectangular patch were 37.6 mm and 61.2 mm (half wavelength) at 2.45 GHz.

$$W = \frac{1}{2f_r \sqrt{\mu_0 \epsilon_0} \sqrt{\epsilon_r + 1}} \sqrt{\frac{2}{\epsilon_r + 1}} \quad (1)$$

To simulate, W and L of the radiating patch were varied. It was found that the change in W influenced the resonant frequency. In other words, as the width W increased, the resonant frequency was shifted to the lower frequency. Moreover, simulations were carried out to determine the optimal position of the feed line as it influences the resonant frequency and the polarization of the antenna. The simulation results revealed that, with the feed line positioned in one of the corners, the resonant frequency was subject to W and the polarization was of horizontal direction. On the other hand, with the feed line positioned at the center, the length of the radiating patch L played a significant part in the resonant frequency while the polarization was of vertical direction [21–23]. The chosen dimensions of the radiating patch were thus 27 mm and 48 mm for W and L , respectively, achieving the resonant frequency at 2.43 GHz with an impedance bandwidth of 70 MHz ($|S_{11}| < -10$ dB).

Due to the narrow impedance bandwidth (i.e. 70 MHz) of the rectangular microstrip antenna and its lowered efficiency as a result of the microstrip feed line, a tuning stub was incorporated into the feed line for improvement of the impedance bandwidth (Fig. 3). In the simulation, p_1 , l_1 and t were varied and the results revealed that p_1 , l_1 and t of 9.75 mm, 9 mm and 3 mm, respectively, could achieve an impedance bandwidth of 88 MHz with the unidirectional radiation pattern.

In the design of the switchable beam rectangular microstrip antenna, two parasitic patches were individually

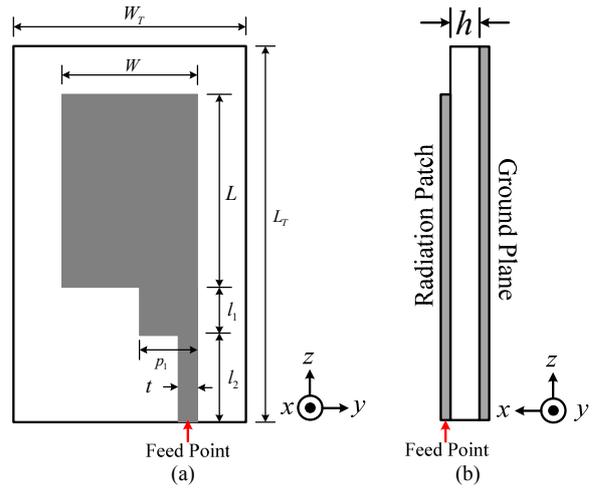

Fig. 3. The schematic of the rectangular microstrip antenna with tuning stub: (a) Top view, (b) side view.

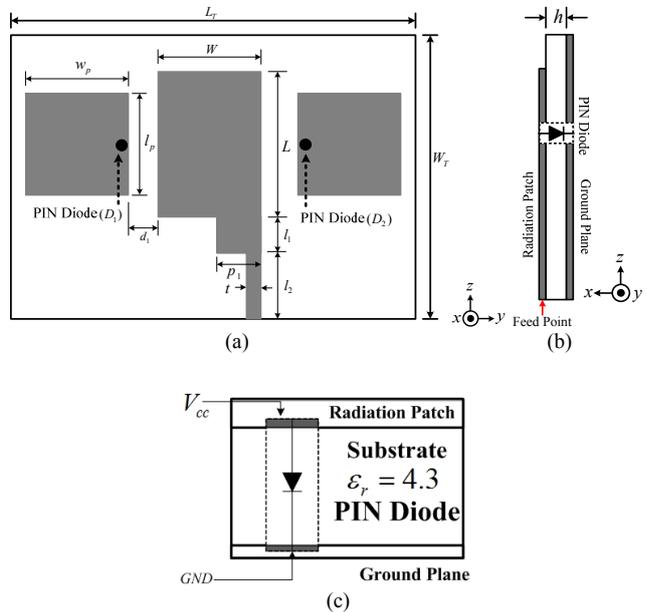

Fig. 4. The schematic of the switchable beam rectangular microstrip antenna: (a) Top view, (b) Side view, (c) Position of PIN diode.

mounted on either side of the radiating patch (Fig. 4(a)). In principle, the introduction of the parasitic patch influences the impedance of the antenna due to the mutual coupling effect between the parasitic and radiating patches. In addition, the distance between the parasitic and radiating patches dictates the radiation pattern. Moreover, two PIN diodes (D_1, D_2) were deployed to short the parasitic patches to the substrate and ground plane. The status of the PIN diodes (i.e. ON or OFF) was manipulated by the DC voltage. Figure 4 illustrates the schematic of the proposed switchable beam rectangular microstrip antenna with double parasitic patches.

Simulations were then carried out and the suitable antenna parameters are tabulated in Tab. 2. In addition, the proposed switchable beam rectangular microstrip antenna with two parasitic patches is operable in three modes:

mode 1 when both PIN diodes (D_1 and D_2) are OFF, mode 2 when D_1 is ON while D_2 is OFF, and mode 3 when D_1 is OFF and D_2 is ON.

Figure 5(a) compares the simulated $|S_{11}|$ of the switchable beam rectangular microstrip antenna with double parasitic patches under the three operation modes. The simulated $|S_{11}|$ varied with the modes of operation but still covered the operating frequency. The xy -plane radiation pattern also varied with the variations in the status of the PIN diodes, where the radiation pattern was directed forward under mode 1 and in the left and right directions

Antenna Parameter	Description	Physical Size (mm)
W_T	Total width	90
L_T	Total length	144
W	Radiation patch width	26.50
L	Radiation patch length	48
p_1	Tuning stub width	12
l_1	Tuning stub length	10
l_2	Microstrip line length	17
t	Microstrip line thickness	3
d_1	Distance between radiation and parasitic patches	8
w_p	Parasitic patch width	32
l_p	Parasitic patch length	30

Mode	PIN Diodes		Direction of Main Beam	Maximum Gain (dBi)
	D_1	D_2		
1	OFF	OFF	0° (Center)	5.6
2	ON	OFF	330° (Left)	6.7
3	OFF	ON	30° (Right)	6.5

Tab. 3. The simulated performance of the proposed antenna under three operation modes.

under modes 2 and 3, respectively. Figure 5(b) illustrates the xy -plane radiation patterns of the switchable beam rectangular microstrip antenna under the three operation modes.

Table 3 summarizes the results of the proposed antenna with regard to the main beam direction and maximum gain under the three operation modes. Under mode 1, the main beam directs at 0° (center) with HPBW of 120° . The main beam directs at 330° (left) with HPBW of 60° under mode 2 and at 30° (right) with HPBW of 60° under mode 3. In addition, $|S_{11}|$ is less than -10 dB along the 2.4–2.5 GHz frequency range under all three operation modes.

4. Gain Enhancement Using Dielectric Slab or MTM

This section examines the deployment of either a dielectric slab or the MTM as the superstrate for enhancement of the antenna gain. In the first scenario, a dielectric slab (i.e. another FR4 substrate) was introduced and mounted onto the switchable beam rectangular microstrip antenna, forming two additional layers of superstrate: free space ($\epsilon_r = 1$) and the additional FR4 ($\epsilon_r = 4.3$).

In Fig. 6, the distance between the antenna and the dielectric slab d was varied between 1–11 mm, and the FR4 thickness was either 1.8 mm or 3.2 mm. It was found that the bandwidth and gain increased with increase in d and that the 3.2 mm-thick FR4 outperformed the 1.8 mm-thick superstrate. Thus, d and the FR4 thickness, respectively, of 10 mm and 3.2 mm were adopted for the improved bandwidth (i.e. 132 MHz) with the maximum gain of 6.2 dBi.

Figures 7(a) and (b) respectively illustrate the simulated radiation patterns and $|S_{11}|$ of the proposed switchable beam rectangular microstrip antenna with dielectric slab under the three operation modes. The simulation results indicated that the main beam of the proposed antenna with dielectric slab could be manipulated in three directions. Under mode 1, the main beam was at 0° (center) with HPBW of 100° , a bandwidth of 132 MHz and a gain of 6.2 dBi. Under mode 2, the main beam was at 330° (left) with HPBW of 50° , a bandwidth of 130 MHz and a gain of 7.30 dBi, while it was at 30° (right) with HPBW of 50° , a bandwidth of 135 MHz and a gain of 7.46 dBi under mode 3. Thus, the dielectric slab could be deployed as the superstrate to improve the bandwidth and gain of the switchable beam rectangular microstrip antenna.

(a)

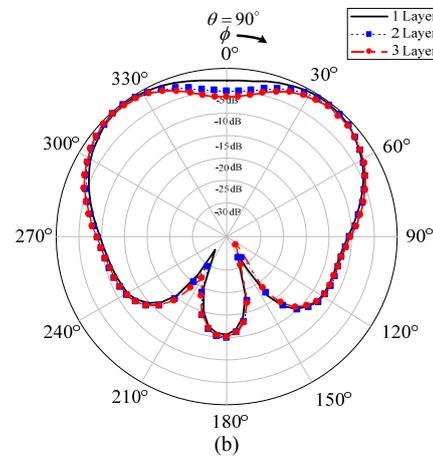

(b)

Fig. 7. Simulated and measured characteristics of the switchable beam rectangular microstrip antenna with dielectric slab under three operation modes: (a) $|S_{11}|$, (b) xy -plane radiation patterns.

In the second scenario, the proposed MTM was utilized as the superstrate of the switchable beam rectangular microstrip antenna to enhance the antenna gain. The MTM was placed in front of the switchable antenna with a distance of 2 mm, as shown in Fig. 8. The arrangement of the planar cycloid diodes (PCD) was such that one MTM block-layer was of 7×17 periodic structure. Simulations were then carried out by increasing the number of MTM block-layers while observing $|S_{11}|$ and the radiation pattern (Fig. 9(a)-(b)).

(a)

(b)

Fig. 9. The simulated characteristics of the switchable beam rectangular microstrip antenna for various MTM block-layers: (a) $|S_{11}|$, (b) xy -plane radiation patterns.

The simulation results revealed that $|S_{11}|$ shifted to the higher resonant frequency with increase in the number of MTM block-layers. In addition, the antenna gain increased with increase in the MTM block-layers, while the beam-width became narrower. This research thus utilized three MTM block-layers so that the final antenna would not be too oversized while achieving the improved antenna gain in relation to the non-MTM antenna.

Further simulations were carried out with the switchable beam rectangular microstrip antenna with three MTM

block-layers under the three operation modes. Figures 10(a) and (b) respectively illustrate the simulated $|S_{11}|$ of the MTM-integrated antenna and the radiation patterns under the three operation modes. Specifically, under mode 1, the main beam directs at 330° and 30° with HPBW of 50° , a bandwidth of 130 MHz and a gain of 6.9 dBi. Under mode 2, the main beam directs at 330° (left) with HPBW of 48° , a bandwidth of 130 MHz and a gain of 7.5 dBi, while the main beam directs at 30° (right) with HPBW of 47° , a bandwidth of 135 MHz and a gain of 7.8 dBi under mode 3. Figure 11 shows the radiation efficiency of the three proposed antennas. The trends of the radiation efficiency for these three antennas are decreased when the frequency is higher. The loss of the FR4 substrate causes the degraded radiation efficiency at the higher frequency. At the frequency of 2.45 GHz, the radiation efficiency of the proposed antenna is 72%. When this structure is added by either the dielectric slab or MTM, the efficiency is increased to 74.5%. It is obvious that the radiation efficiency of the proposed antenna with either the dielectric slab or MTM is better than the proposed antenna without superstrate. The additional superstrate (dielectric slab or MTM) can improve the radiation efficiency over the relevant range of frequencies because the losses of surface waves are reduced. It is an inherent anisotropy of the additional structure and back-wave in superstrate.

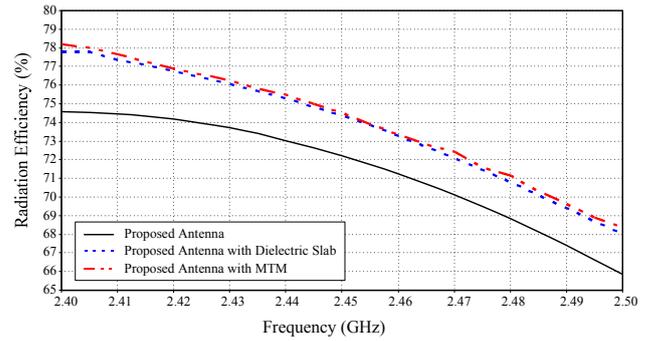

Fig. 11. The simulated radiation efficiency of the three proposed antennas.

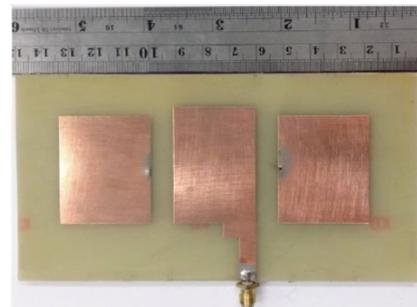

Fig. 12. Prototype of the switchable beam rectangular microstrip antenna.

5. Experimental Results

To verify, three prototype antennas were fabricated and experiments undertaken. The three prototype antennas were the proposed switchable beam rectangular microstrip antenna, the proposed antenna with either the dielectric slab or MTM.

Figure 12 depicts the prototype of the switchable beam rectangular microstrip antenna with two parasitic patches on a 3.2 mm-thick FR4 substrate ($\epsilon_r = 4.3$). Two PIN diodes with R_{on} of 1.8Ω and C_{on} of 9.3 pF were deployed to affix the parasitic patches to the substrate and the ground plane. The experimental results revealed that the proposed switchable beam rectangular microstrip antenna could achieve a bandwidth of 120 MHz. In addition, the xy -plane radiation patterns under the three operation modes were as follows: under mode 1, the direction of the main beam was of 0° with HPBW of 120° and the maximum gain of 5.6 dBi; under mode 2, the direction was of 330° with HPBW of 60° and the maximum gain of 6.7 dBi; and under mode 3, the direction was of 30° with HPBW of 60° and the maximum gain of 6.5 dBi (Fig. 5(a), (b)).

The second prototype antenna was the switchable beam rectangular microstrip antenna with dielectric slab as the superstrate with the distance between the antenna and the slab of 10 mm. This antenna dimension is $90 \text{ mm} \times 144 \text{ mm} \times 16.4 \text{ mm}$. In Fig. 7(a), the prototype antenna with the dielectric slab could achieve a bandwidth of 200 MHz. In addition, the xy -plane radiation patterns under the 3 operation modes are as follows: under mode 1

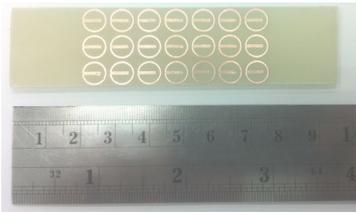

Fig. 13. Periodic structure of planar cycloid dipoles.

the direction of the main beam was of 0° with HPBW of 100° and the maximum gain of 6.2 dBi; under mode 2, the direction was of 330° with HPBW of 50° and the maximum gain of 7.3 dBi; and under mode 3, the direction was of 30° with HPBW of 50° and the maximum gain of 7.46 dBi (Fig. 7(b)).

The third prototype antenna was the switchable beam rectangular microstrip antenna with three MTM block-layers, as shown in Fig. 13. The antenna size is $90\text{ mm} \times 144\text{ mm} \times 29.2\text{ mm}$. The prototype antenna with three MTM block-layers could achieve a bandwidth of 150 MHz. The xy -plane radiation patterns under the three operation modes are as follows: under mode 1, the directions of the main beam were of 30° and 330° with HPBW of 50° and the maximum gain of 6.9 dBi; under mode 2, the direction was of 330° with HPBW of 48° and the maximum gain of 7.5 dBi; and under mode 3, the direction was of 30° with HPBW of 47° and the maximum gain of 7.8 dBi (Fig. 10(a), (b)).

Mode	Prototype Antenna			Prototype Antenna with Dielectric Slab			Prototype Antenna with MTM		
	Direction of Main Beam	HPBW	Maximum Gain (dBi)	Direction of Main Beam	HPBW	Maximum Gain (dBi)	Direction of Main Beam	HPBW	Maximum Gain (dBi)
1	0°	120°	5.6	0°	100°	6.2	330° and 30°	50°	6.9
2	330°	60°	6.7	330°	50°	7.3	330°	48°	7.5
3	30°	60°	6.5	30°	50°	7.46	30°	47°	7.8

The measured results indicated that the switchable beam rectangular microstrip antennas of all three configurations were operable under all three operation modes along the 2.4–2.5 GHz frequency range. Table 4 compares the performances of the three prototype antennas and it is evident that the deployment of either the dielectric slab or MTM as the superstrate could enhance the antenna gain.

6. Conclusions

This research has presented the switchable beam rectangular microstrip antenna in which two PIN diodes were deployed for manipulation of the main beam direction and the superstrate (i.e. either a dielectric slab or the MTM) for enhancement of the antenna gain. In this research, the dielectric slab is a second FR4 substrate while the metamaterial (MTM) is the 7×17 periodic structure of planar cycloid dipoles (PCD). The proposed switchable antennas with and without the superstrate are operable in the 2.4–2.5 GHz WLAN system and switchable in three directions of 0° , 30° and 330° (xy -plane). The simulation and experimental results validate the applicability of the dielectric slab and three MTM block-layers as the superstrate to improve the antenna gain. In addition, the proposed superstrate-integrated switchable beam rectangular microstrip antenna could be employed in the point-to-point and point-to-multipoint applications.

About the Authors ...

Supakit KAWDUNGTA received the Bachelor of Engineering (2006) in Telecommunications Engineering, Master of Engineering (2007) in Telecommunications Engineering and Doctor of Engineering (2011) in Electrical Engineering from King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand. From 2011 to present, he is an Assistant Professor in electronic and telecommunications engineering, Rajamangala University of Technology Lanna, Chiang Mai, Thailand.

Puwanai JAIBANAUEM received the Bachelor of Engineering (2016) in Electronic Engineering from Rajamangala University of Technology Lanna, Chiang Mai, Thailand. From 2016 to present, he is an engineer in Advanced Info Service PLC., Chiang Mai, Thailand.

Rattiya PONGGA received the Bachelor of Engineering (2015) in Electronic Engineering from Rajamangala University of Technology Lanna, Chiang Mai, Thailand. From 2015 to present, she is an engineer in Thai NJR Co., Ltd., Lamphun, Thailand.

Chuwong PHONGCHAROENPANICH received the Bachelor of Engineering (Hons), Master of Engineering, and Doctor of Engineering degrees from the Faculty of Engineering, King Mongkut's Institute of Technology Ladkrabang (KMITL), Bangkok, Thailand, in 1996, 1998, and 2001, respectively. He is currently an Associate Professor at the Department of Telecommunications Engineering, KMITL where he also serves as the Leader of the Wireless Communication Laboratory at the same institute. He was the board committee of ECTI Association in 2008–2011. He serves as the chair of IEEE MTT/AP/ED Thailand chapter. He is the associate editor of IEICE Trans. Com. and ECTI Trans. EEC. He has been the organizing committee of several international conferences including the TPC chair of 2009 International Symposium on Antennas and Propagation (ISAP2009) and TPC member of ISAP2012. He is the reviewer of many journals including IEEE Trans. Antennas and Propagation and Electronics Letters, ECTI Trans. and many international conferences including ISAP and Asia-Pacific Microwave Conference (APMC). His research interests are antenna design for various mobile and wireless communications, conformal antennas and array antenna theory. Dr. Phongcharoenpanich is a Member of IEEE, IEICE and ECTI.
